the results of running the W3C Validator on the Lab110 group's HTML show that there is no errors or warnings to show.

According to Web Content Accessibility Guidelines, we can find some issues of the webpage of lab110, and solutions respectively.

For the Guideline 1.1 from Principle 1, the page meets the requirements for success criteria level A. Because for each of images in the table, a text alternative that serves the equivalent purpose is provided. Hence, G196 technique for situation A, which is If a short description can serve the same purpose and present the same information as the non-text content, is sufficient.

For the Guideline 1.3 from Principle 1, the page meets the requirements for success criteria level A. In terms of Info and Relationships, the page Indicates new content with boldface and a text indicator, hence G117 technique is sufficient. In terms of Meaningful Sequence, the page orders the content, such as image, author, tags, description in the table, in a meaningful sequence, hence G57 technique is sufficient. In terms of Sensory Characteristics, a button of submitting new author is provided, this includes both shape and textual information to locate the button, hence G96 technique is sufficient.

For the Guideline 1.4 from Principle 1, the page meets the requirements for success criteria level A. Because it ensure that information conveyed by color differences is also available in text, for example, the link of Not Without Laughter is in the same color as the cover of the book, which is different with the color of links of other books. Hence, G14 technique is sufficient.

For the Guideline 2.1 from Principle 2, the page does not meet the requirements for success criteria level A. Because the only way to open links is clicking the mouse. Hence, F42 technique is sufficient, and the page fails to comply to the Guideline 2.1. To solve this issue, the link functionality can be invoked with the mouse, or via the Enter key if the user agent includes the element in the tab chain.

For the Guideline 2.4 from Principle 2, the page does not meet the requirements for success criteria level A. Because there is a failure that occurs when the tab order does not follow logical relationships and sequences in the content. For instance, Leo Tolstoy is at 4th position in the table of Photo Album, but the picture of his work, which is War and Peace, is at 1st position in the table of Example Of Works By These Authors. Hence, F44 technique is sufficient, and the page fails to comply to the Guideline 2.4. To solve this issue, the order of works can be changed to the same as the order of authors.

By testing the responsiveness of the webpage of lab110 between different devices, I found that the webpage of lab110 has been optimized accordingly for different devices. For mobile devices, the webpage of lab110 has been adjusted in terms of table layout and the number of characters per line. In the aspect of table layout, the webpage of lab110 has changed from the horizontal table arrangement on the desktop to the vertical table arrangement on the mobile terminal, so as to ensure that users can browse all the tables on any device without dragging the horizontal scroll bar. In terms of the number of characters per line, in order to

adapt to devices with different aspect ratios of screens, the number of characters per line will also vary to ensure that users can browse all the characters without dragging the horizontal scroll bar.

The responsiveness of the webpage of lab110 to different devices is generally excellent. However, when using mobile terminals to browse the webpage of lab110, there will still be a horizontal scroll bar. Although the user can read all the content without dragging the horizontal scroll bar, it is possible that the user drags the horizontal scroll bar by mistake, which affects the reading experience. This is a point that can be improved.

The webpage of lab110 is organized semantically. The document structure tags, for example, head tags and body tags, are used properly. The textual meaning of heading element tags is used properly, and there is also proper use of strong tags which giving texts added importance. In addition, Correlation Tags are used in a proper way, for instance, ordered list tags are used to list factors of being a good author in the section of Purpose Of This Album, and unsorted list tags are used to state the tags of authors, which have no order in the table. Besides, the use of section tags is also clear.

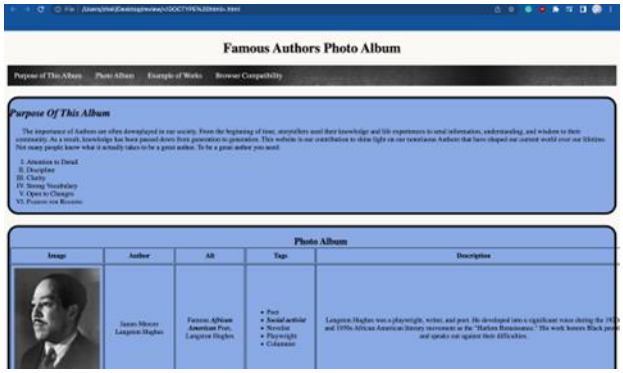

Before discussing whether to prioritize mobile or desktop, we should first understand the difference between the two.

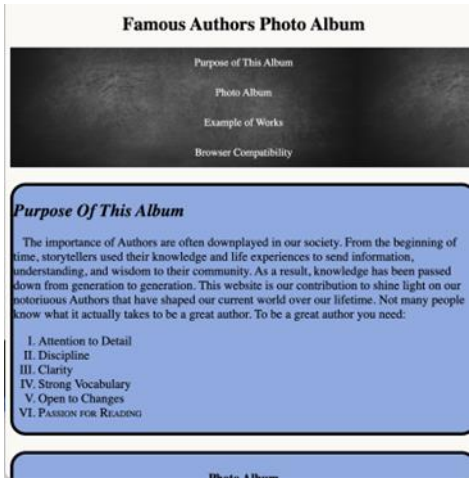

Mobile-first design is when planning and developing a website with mobile users in mind first. In 2021, mobile Internet users have reached 4.28 billion, accounting for about 92% of the total Internet users. This also clearly shows that in today's world, the use of mobile devices to access web Users have far surpassed before. Web pages should be more prioritized over mobile devices, such as mobile phones and tablets.

Also, opening desktop websites on mobile devices can sometimes be difficult. This could be due to a large amount of data on the website, a limited data plan, etc. All these factors can be addressed with mobile-first website design and provide users with a better, minimal and lean website. This also affects the size of the web page, and the css code will also change accordingly.

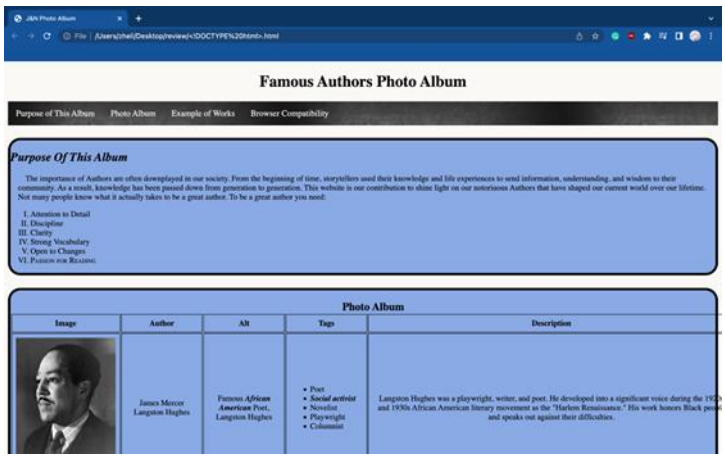

But at the same time, there will also be disadvantages. The most obvious point is that developers use desktop computers to complete it, so it is natural to want to Adapt to desktop devices. So developers need to overcome the fixed thinking of wanting web pages to adapt to desktops.

In the webpage of the lab110 group, they showed their responsive design very well (as shown below in photos). but it is clear that they are more inclined to desktop design, because in the table of Photo Album, you can only intuitively compare picture and texts of different author on desktop. If you are a mobile device user, all contents are vertically arranged which is not suited for comparison.

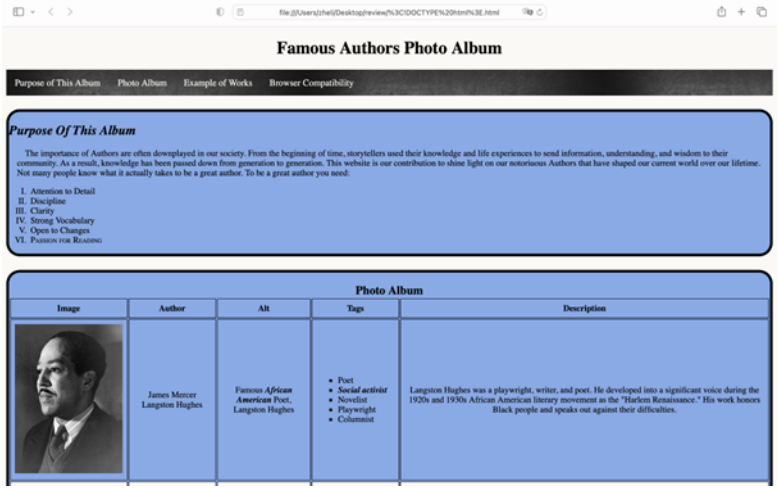

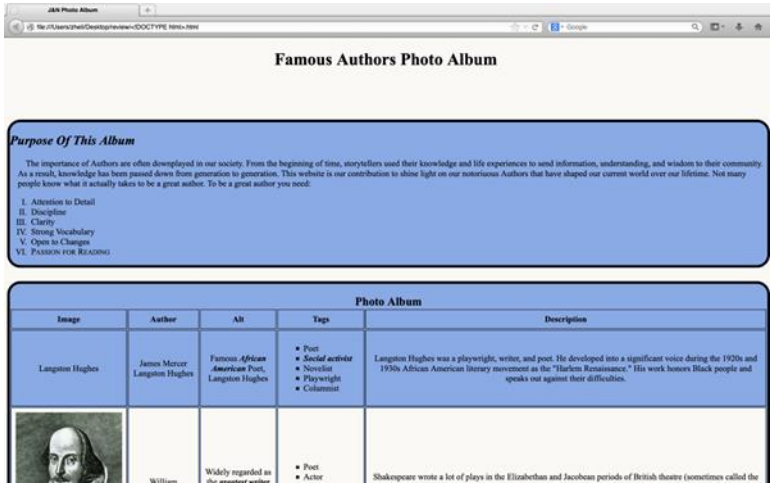

Accessibility on Google Chorme:

Accessibility on Safari:

Accessibility on Firefox:

The above is their accessibility to the three browsers (Google Chorme, Safari and Firefox). It can be seen that there will be a slight difference on Firefox, because the title is not displayed. But both Google Chorme and Safari respond well.

From my personal perspective, this homework of lab110 is done well. Because there is no big problem with the structure and design of the website. In terms of content, in the tags table of the third author Primo Levi, the position of the fifth tag appears a little Deviation. And there are several CSS constructs which are not used, they are border-style, border-spacing, font-weight, font, list-style-image. The rest is handled well. Especially finding a representative work for each author and uploading the picture of the book.

Besides, as mentioned earlier, there are some problems with the accessibility of Firefox browser. The background of the four subtitles in the <nav> section is not displayed.

After reviewing the assignment from lab110, I learn a lot. They choose a relatively complex

background instead of a monotonous solid color, and they match colors well. The combination of black and blue is stylish and impressive, these are details I can learn from the design. In addition, I was not aware of hierarchical structure, but they show me an excellent example of dealing with layout. The other thing I ignored is the match of picture and its link. They color the link of Not Without Laughter red, which perfectly matches the color of the book cover. Also, I did not think of responsive catalogue until I saw their catalogue, which leads you to corresponding contents by clicking index titles.
